Given a `pattern` and a string `s`, return `true` if `s` **matches** the `pattern`.

A string `s` **matches** a `pattern` if there is some **bijective mapping** of single characters to strings such that if each character in `pattern` is replaced by the string it maps to, then the resulting string is `s`. A **bijective mapping** means that no two characters map to the same string, and no character maps to two different strings.

Example 1:

Input: `pattern = "abab", s = "redblueredblue"`

Output: `true`

Explanation: One possible mapping is as follows:

'a' -> "red"

'b' -> "blue"

Example 2:

Input: `pattern = "aaaa", s = "asdadasdasd"`

Output: `true`

Explanation: One possible mapping is as follows:

'a' -> "asd"

Example 3:

Input: `pattern = "aabb", s = "xyzabcxzyabc"`

Output: `false`

Constraints:

- 1 <= `pattern.length`, `s.length` <= 20
- `pattern` and `s` consist of only lowercase English letters.

```

1 class Solution {
2 public:
3     bool isPatternMatch(string &pattern, string &s, unordered_map<char, string> &mp, int i, int j, unordered_map<char, string> &used) {
4         if (i == pattern.size() & j == s.size()) return true;
5         if (i < pattern.size() & j < s.size()) {
6             char p = pattern[i];
7             string s_sub = s.substr(j, s.size() - j);
8             if (mp.find(p) != mp.end() & mp[p] == s_sub) {
9                 return isPatternMatch(pattern, s, mp, i + 1, j + s_sub.size(), used);
10            }
11            if (mp.find(p) == mp.end() & !used.find(p)) {
12                mp[p] = s_sub;
13                used[p] = true;
14                if (isPatternMatch(pattern, s, mp, i + 1, j + s_sub.size(), used)) return true;
15                mp.erase(p);
16                used.erase(p);
17            }
18        }
19        return false;
20    }
21};
